BMP Newsletter

Best Management Practices for Water Quality & Soil Conservation

This issue's cover photo was taken at Singletary Lake State Park during the Bottomland and Swamp Forests Symposium field tour (photo credit: Barry New). Topics of discussion at this site were Carolina Bays: formation, ecological importance, and succession.

How do you think Carolina Bays were formed? A question scientists have debated for years.

Bottomland and Swamp Forests Symposium

Bottomland and swamp forests often provide crucial wetland functions such as transpiration, photosynthesis, nutrient cycling, net primary productivity, among many others. They are valued by society for their fiber production, improvement of water quality, flood storage, and aesthetic and heritage value.

An example of a swamp forest that provides ecological functions that society values.

In late October-early November the N.C. Forest Service and N.C. State University hosted a Bottomland and Swamp Forest Symposium in Wilmington. The friendly atmosphere showcased research results and discussed perspectives of bottomland forest management and landowner objectives. Over 150 were in attendance and representation from over 50 agencies and businesses present.

Bottomland Forests and Water Quality

Historically, concerns regarding timber harvests of bottomlands and swamp areas were not water quality related, rather the concerns were regarding water movement through the stand, stand regeneration, and site productivity.

Bottomlands have long histories of repeated timber harvests and can recover from human disturbances. Silviculture within these systems can and has been sustainable, but there is not a simple 'one size fits all' prescription. Swamps vary considerably depending on how water flows through the site (stagnant vs moving), how fertile/non-fertile soils are, as well as how long and to what depth the site is flooded. Floodplain ecosystems are always changing (either rapidly or gradually).

Managers providing silvicultural harvest prescriptions (seed-tree, clearcuts, shelterwood, etc.) and regeneration approaches (natural vs. artificial) consider water movement at stand and landscape levels during preharvest planning to select an appropriate strategy. Maintaining the naturally existing flow system increases the likelihood of natural regeneration success.

Timber harvesting in bottomlands inherently involves BMPs. For sound forest management in bottomlands, managers should:

- Know the federal and state rules
- Know the agencies that regulate wetlands
- Know when to ask for help
- Preharvest plan
- Harvest when relatively dry
- Minimize adverse impacts on water quality, both onsite and offsite
- Protect hydrologic functions
- Protect soil physical properties
- Select tree species that fit site conditions
